PYRIMIDINE CARBOXYLATES AND RELATED COMPOUNDS AND
METHODS FOR TREATING INFLAMMATORY CONDITIONS

TECHNICAL FIELD

5 The present invention relates generally to compounds that block intracellular signal transduction and activation of transcription factors, and to methods for preventing or treating immunoinflammatory and autoimmune diseases.

BACKGROUND OF THE INVENTION

10 Signals necessary for cell growth, differentiation, response to bioregulatory molecules, infectious agents and physiological stress involve changes in the rates of gene expression. The ability to respond appropriately to such signaling events challenge the survival of the cell and ultimately the organism. Perturbations in the normal regulation of these specific genetic responses can result in pathogenic events
15 which lead to acute and chronic disease.

 In certain autoimmune diseases or chronic inflammatory states, continuous activation of T-cells eventually leads to a self-perpetuating destruction of normal tissues or organs. This is caused by the induction of adhesion molecules, chemotaxis of leukocytes, activation of leukocytes and the production of mediators of
20 inflammation. All of these events are regulated at the level of transcription for the production of new proteins, including cytokines. The production of cytokines, as well as a number of other cellular regulators, is controlled by a family of proteins known as transcription factors (TFs). These transcription factors, when activated, bind to specific regions on the DNA and act as molecular switches or messengers to induce or
25 upregulate gene expression. The activation of these TFs is caused by a variety of external signals including physiological stress, infectious agents and other bioregulatory molecules. Once the plasma membrane receptors are activated, a cascade of protein kinases and second messengers are induced which, in turn, result in the production of RNA transcripts. The end result is the production of proinflammatory proteins via
30 translation and processing of the RNA transcripts.

This activation system can, at times, be very robust. For example, a specific set of external signals could result in a single transcription factor to induce many proteins responsible for a given disease. Therefore, regulating this process by disrupting the production of activated TF(s) has the potential to attenuate the production of the associated pathological proteins, thereby halting or reversing the course of the disease.

Two transcription factors, NF κ B and AP-1, have been shown to regulate the production of many proinflammatory cytokines and related proteins that are elevated in immunoinflammatory diseases. These TFs regulate interleukin-1 (IL-1), interleukin-2 (IL-2), tumor necrosis factor- α (TNF α), interleukin-6 (IL-6) and interleukin-8 (IL-8) levels in a variety of cell types. For example, NF κ B and other related complexes are involved in the rapid induction of genes whose products function in protective and proliferative responses upon exposure of cells to external stimuli. Similarly, AP-1 has a significant role in the regulation of interleukin-2 (IL-2) and tumor necrosis factor- α (TNF- α) transcription during T-cell activation. In addition, TNF- α and IL-1 are strong activators of collagenase, gelatinase and stromelysin gene expression, which require a single AP-1 binding site in the promoter region of these genes. Therefore, an inhibitor of NF κ B and/or AP-1 activation would coordinately repress the activities of a series of proteinases. In addition, cell adhesion molecules are also controlled by these TFs. All of these proteins have been shown to play a role in diseases, including osteoarthritis, transplant rejection, ischemia, reperfusion injury, trauma, certain cancers and viral disorders, and autoimmune diseases such as rheumatoid arthritis, multiple sclerosis, psoriasis, inflammatory bowel disease, glomerulonephritis, lupus and juvenile diabetes. In summary, the role of these TFs is to act as a transducer for certain stimuli that lead to immune, inflammatory, and acute phase responses.

Since many diseases are caused by the inappropriate production of proteins, conventional therapeutic approaches have focused on inhibiting function or activity of individual effector proteins. These treatments have not always proved to be effective and, at times, are associated with many undesirable side effects. Therefore,

there is a need for new therapies for the prevention and/or treatment of immunoinflammatory and autoimmune diseases. More specifically, there is a need for compounds that prevent, preferably by inhibiting transcription at an early stage, the production of proteins associated with immunoinflammatory and autoimmune diseases.

5 Furthermore, these compounds should inhibit the kinase(s) that regulate the activation of TFs such as NF κ B and AP-1. The present invention fulfills these needs and provides further related advantages.

SUMMARY OF THE INVENTION

10 In brief, this invention is directed to compounds that block the activation of transcription factors (TFs), particularly NF κ B and AP-1, and are believed to function through inhibition of a family of specific kinases. This results in a decrease in a number of proinflammatory proteins, including IL-1, IL-2, IL-8 and/or TNF α , which are responsible for tissue and organ damage associated with diseases such as rheumatoid

15 arthritis, osteoarthritis, related autoimmune disorders and tissue rejection. Accordingly, compounds of the present invention are useful in, for example, the prevention of organ and tissue rejection associated with transplantation. Furthermore, the compounds of this invention also have utility in the prevention and/or treatment of immunoinflammatory and autoimmune diseases, as well as having general activity as

20 anti-inflammatory agents.

DETAILED DESCRIPTION OF THE INVENTION

As mentioned above, the compounds of this invention block activation of transcription factors (TFs), and thus have utility as anti-inflammatory agents in general, and in the prevention and/or treatment of a variety of conditions, including (but not
25 limited to) immunoinflammatory and autoimmune diseases. The compounds are believed to function by inhibiting, at an early stage, transcription of deleterious proteins associated with such conditions or diseases. It is believed that this is achieved by inhibiting the kinase(s) that regulate the activation of TFs, such as NF κ B and/or AP-1. By disrupting the production of these activated TFs, synthesis of pathological proteins,
30 including proinflammatory cytokines, associated with a series of immunoinflammatory and autoimmune diseases are effectively blocked at a transcriptional level.

Accordingly, the compounds of this invention have activity in both the prevention and treatment of immunoinflammatory diseases such as rheumatoid arthritis, osteoarthritis and transplant rejection (tissue and organ), as well as autoimmune diseases such as multiple sclerosis.

The compounds of this invention further include pharmaceutically and prophylactically acceptable salts of compounds of structure (I). Compounds of structure (I) may contain proton donating groups (*e.g.*, a carboxylic acid group) and/or proton accepting groups (*e.g.*, a group with a nitrogen atom having a free lone pair of electrons, such as an amine group), and the salts of compounds of structure (I) may be formed and utilized in the practice of the invention. Thus, compounds of the invention may be in the form of a base addition salt (*i.e.*, a salt of a proton donating group) or in the form of an acid addition salt (*i.e.*, a salt of a proton accepting group), as well as the free acid or free base forms thereof.

Acid addition salts of a free base amino compound of the invention may be prepared by methods well known in the art, and may be formed from organic and inorganic acids. Suitable organic acids include acetic, ascorbic, benzenesulfonic, benzoic, fumaric, maleic, methanesulfonic, and succinic acids. Suitable inorganic acids include hydrochloric, hydrobromic, sulfuric, phosphoric and nitric acids. Base addition salts of a free acid carboxylic acid compound of the invention may also be prepared by methods well known in the art, and may be formed from organic and inorganic bases. Thus, the compounds of this invention also include those salts derived from inorganic bases such as the hydroxide or other salt of sodium, potassium, lithium, ammonium, calcium, magnesium, iron, zinc, copper, manganese, aluminum, and the like, and organic bases such as substituted ammonium salts.

The compounds of this invention may be made by one skilled in organic synthesis by known techniques, as well as by the synthetic routes disclosed herein. Referring to Figure 1, the compounds of this invention may be made from commercially available β -keto esters **1** by heating at elevated temperatures (75-110°C) with a mixture of urea and triethylorthoformate (or a substituted orthoformate) to provide ureido derivatives **2**. Treatment of these intermediates with sodium alkoxides, such as sodium ethoxide in an alcoholic solvent at 35-100°C, gives 2-hydroxypyrimidine esters **3** which, upon treatment with a chlorinating agent such as phosphorous oxychloride at elevated temperatures (75-120°C), yields 2-chloropyrimidine esters **4**.

Compound **4** may be reacted with various nucleophiles in an aprotic solvent at ambient temperature to provide derivatives **7**. Compound **4** may also be converted to the carbonyl chloride **5** by treatment with base, such as hydroxide in water, followed by a chlorinating agent, such as oxalyl chloride in methylene chloride. Compound **5** can be treated with an organometallic, such as methyl magnesium bromide in a solvent such as THF or ether at -35°C to -65°C, to give ketone **9**. This ketone may be treated with various nucleophiles in an aprotic solvent and at ambient temperature to provide compound **10**.

Alternatively, compound **3** may be converted to the hydroxy carboxylic acid **6** by treatment with a strong base, such as sodium hydroxide, or strong acid, such as HCl, at elevated temperature (70-110°C). The hydroxy carboxylic acids may be converted to the chloro carbonyl chloride with thionyl chloride and/or phosphorous oxychloride.

Compound **4** can also be treated with hydrazine at ambient temperature in a solvent, such as THF, with pyridine as a catalyst to provide the intermediates of structure **8**. These hydrazino derivatives can be reacted with cyclic anhydrides, such as citraconic anhydride, in a solvent, such as chloroform, at elevated temperatures (35-65°C) to provide compounds of structure **11**. Subsequent treatment of **11** with a strong base, such as sodium hydride, in an aprotic solvent, such as THF, at ambient temperature followed by an alkyl iodide, such as methyl iodide, provides the alkylated derivatives of structure **12**.

Compounds of structures (VI) and (VII) may be prepared by reducing any of the compounds in Figure 1 so as to convert a carboxylate group to a methylol (-CH₂OH) group. Lithium aluminum hydride is a suitable reducing agent. In any event, the methylol group may, if desired, be converted to -CH₂OR, by standard alkylation chemistry (*e.g.*, using a strong base and a nucleophile).

Referring to Figure 2, an alternative synthetic procedure is disclosed. In this procedure, commercially available diethyl ethoxymethylenemalonate **13** is treated with an amidine, such as trifluoromethylamidine, in a protic solvent, such as ethanol, in the presence of an alkoxide, such as NaOEt, at elevated temperatures (75-110°C) to give the hydroxy pyrimidine ester **14**. Chlorination with a chlorinating agent, such as POCl₃ or thionyl chloride, yields the chloroester derivative **15** which can be treated with various amines at ambient temperature in an aprotic solvent, such as THF, to provide the substituted pyrimidines **16**. Derivative **15** may also be treated with hydrazine in a solvent such as THF in the presence of pyridine to give the hydrazino intermediates **17**. Treatment of **17** with various cyclic anhydrides, such as citraconic anhydride, in a solvent, such as chloroform, at elevated temperatures (34-65°C) provide compounds of structure **18**. Alkylation of these compounds with a hydride, such as sodium hydride,

followed by an alkyl halide in an aprotic solvent, such as THF, gives the alkylated derivatives of structure 19.

Again, compounds of structures (VI) and (VII) may be prepared from the corresponding carboxylate compounds as discussed above in connection with Figure 1.

5 Compounds of the invention wherein R_9 is $-C(=O)R_7$ may be prepared from the corresponding compound wherein R_9 is hydrogen (as prepared according to either of Figure 1 or 2) using standard acylation chemistry. For example, a compound having R_9 equal to hydrogen may be treated with a strong base (*e.g.*, NaH), followed by an acylating agent (*e.g.*, $Cl-C(=O)R_7$).

10 Once synthesized, the compounds of this invention may be formulated for administration to a warm-blooded animal by a variety of techniques known to those skilled in the art. In one embodiment, the compound is in the form of a pharmaceutical composition for prophylactic or therapeutic use, and which contains at least one compound of this invention in combination with a pharmaceutically acceptable carrier
15 or diluent. The compound is present in the composition in an amount which, upon administration to the animal, is effective in preventing or treating the condition of interest. Preferably, the composition includes a compound of this invention in an amount ranging from 0.01 mg to 250 mg per dosage, depending upon the route of administration, and more preferably from 1 mg to 60 mg. Appropriate concentrations,
20 dosages and modes of administration may be readily determined by one skilled in the art.

Suitable carriers or diluents are familiar to those skilled in the formulation field. For compositions formulated as liquid solutions, acceptable carrier or diluents include saline and sterile water, and may optionally include antioxidants,
25 buffers, bacteriostats and other common additives. The compositions of this invention may also be formulated as pills, capsules, granules or tablets which contain, in addition to the compound of this invention, diluents, dispersing and surface active agents, binders and lubricants. One skilled in the art may further formulate the compounds of this invention in any appropriate manner, and in accordance with accepted practices,

such as those disclosed in *Remington's Pharmaceutical Sciences*, Gennaro, Ed., Mack Publishing Co., Easton, PA, 1990 (incorporated herein by reference).

In another embodiment, the present invention provides methods for preventing or treating a variety of conditions. Such methods include administering a compound of this invention to a warm-blooded animal in need thereof in an amount
5 sufficient to prevent or treat the condition. Such methods include systemic administration of a compound of this invention, preferably in the form of a composition as disclosed above. As used herein, systemic administration includes oral and parental methods of administration. For oral administration, suitable pharmaceutical
10 compositions include powders, granules, pills, tablets and capsules, as well as liquids, syrups, suspensions and emulsions. These compositions may also include flavorants, preservatives, suspending, thickening and emulsifying agents, and other pharmaceutically acceptable additives. For parental administration, the compounds of the present invention may be prepared in aqueous injectable solutions which may
15 contain, in addition to the compound of this invention, buffers, antioxidants, bacteriostats and other additives commonly employed in such solutions.

As mentioned above, compounds of the present invention can be used to prevent or treat a wide variety of disorders, diseases and/or illnesses. In particular, the compounds may be administered to a warm-blooded animal for prevention or treatment
20 of rheumatoid arthritis, osteoarthritis, tissue and/or organ transplant rejection, sepsis, ARDS, asthma, trauma, oxidative stress, cell death, irradiation damage, ischemia, reperfusion, cancer, viral infection, and autoimmune diseases such as psoriasis, inflammatory bowel disease, glomerulonephritis, lupus, uveitis and chronic hepatitis.

Compounds of this invention may be screened by known and accepted
25 techniques for their ability to function as prophylactically and/or therapeutically active agents. For example, the compounds may be evaluated in *in vitro* and/or *in vivo* assays indicative of the compound's anti-inflammatory and immunosuppressive properties. To this end, such compounds may first be evaluated in a number of cell-based assays which determine the ability of a compound to prevent activation of NF κ B and AP-1 (*see*
30 Example 126). Next, the compound's ability to attenuate cytokine levels (such as IL-2

and IL-8), which are known to be elevated in certain disease states, may be determined (see Example 127). The compounds may then be evaluated in an appropriate animal model, including rodent models of inflammation and immunosuppression (see Example 128).

5 It should be recognized that, for example, in the case of immunosuppressive drugs and other agents which have utility for the treatment of rheumatoid arthritis (RA), numerous studies have been performed directed to the activity of such drugs. To this end, cyclosporin A has been used in clinical trials since the late 1970's as a second-line drug, and is recommended to be used only in patients
10 with active RA. Thus, Experiment 128 may be performed utilizing cyclosporin A as a positive control. A recent review of such immunosuppressive drugs, including relevant assays for the same, is presented by R.P. Carlson in *Exp. Opin. Invest. Drugs* 4(9):853-859, 1995 (incorporated herein by reference in its entirety, including cited references).

 The following examples are presented for purpose of illustration, not

SYNTHESIS OF REPRESENTATIVE COMPOUNDS

BY COMBINATORIAL CHEMISTRY TECHNIQUES

This example illustrates the synthesis of a representative class of compounds of this invention, 2-substituted-4-trifluoromethyl-5-pyrimidine carboxylic acid methyl esters, by combinatorial chemistry. It should be understood that, while a specific class of compounds are illustrated in this example, the following procedure may be employed to synthesize other compounds of this invention.

A mixture of TentaGel resin (TentaGel S PHB, Advanced Chem Tec Louisville, Kentucky, 17 g, 0.2 mmol/g reactive sites) containing a free hydroxy as the reactive site and DMF (75 mL) was stored for 0.25 h. Then a solution of 2-chloro-4-trifluoromethyl pyrimidine-5-carbonyl chloride (2.20 g, 10.2 mmol) in DMF (15 mL) was added. The mixture was gently shaken for 3 h and filtered. The resin was washed thoroughly with DMF (3 X100 mL) and CH_2Cl_2 (3 X100 mL) and then dried under vacuum. The resin was divided into 80 equal portions and placed into 80 separate reaction vessels (dispersion tubes). The dispersion tubes were placed into separate test tubes each containing a different amine (2.5 mmol, Appendix I) and 2 mL of a 0.1M solution of pyridine/DMF (5 molar equivalents of each amine in each test tube). The entire set of 80 reaction vessels was gently shaken for 5 hours to ensure complete reaction. Then each of the dispersion tubes was removed from the test tube containing the amine and rinsed separately to remove any unreacted materials. The dispersion tubes were then dried and submersed into 80 new test tubes (previously tared), each containing a solution of NaOMe (2.5 mL, 0.012 M solution, 0.03 mmol). The reaction

was allowed to proceed overnight at room temperature under N₂. Then the dispersion tubes were removed from the solution and individually rinsed with MeOH. The individual MeOH solutions were concentrated in the tared test tubes to provide known amounts of the desired 80 individual methyl esters substituted with different groups at the 2-position. Each compound was >85% pure by HPLC and had the correct molecular weight as determined by GC/MS.

INHIBITION OF THE ACTIVATION OF NFκB AND AP-1

10 A. NFκB ASSAY

Stable human Jurkat T-cells containing an NFκB binding site (from the MHC promoter) fused to a minimal SV-40 promoter driving luciferase expression were used in this experiment. Cells were split to 3 x 10⁵ cells/mL every 2-3 days (cell concentration should not exceed 1 x 10⁶ cells/mL to keep the cells proliferating in log phase). These cells were counted, resuspended in fresh medium containing 10% Serum-Plus at a density of 1 x 10⁶ cells/mL and plated in 96 well round bottom plates (200 μL per well) 18 hours prior to starting the experiment.

Compounds of this invention, dissolved in dimethyl sulfoxide (3.3, 0.33 and 0.03 μg/mL), were then added to the 96 well plates containing the cells and the plates were incubated for 0.5 h at 37°C. Then 50 ng/mL of phorbol 12-myristate-13-acetate (PMA) and 1 μg/mL of phytohemagglutinin (PHA) were added to each well and the cells were incubated for an additional 5 h at 37°C. The plates were centrifuged at 2200 RPM for 3 minutes at room temperature and then the medium was removed. To each well was added 60 μL of cell lysis buffer and the plates were left at room temperature for 0.25 h. Then 40 μL of each cell extract was transferred to a black 96 well plate and 50 μL of luciferase substrate buffer was added. Luminescence was immediately measured using a Packard TopCount.

B. AP-1 ASSAY

For AP-1, the assay was run as described above for NFκB except stable Jurkat T-cells were used that contained a collagenase promoter driving luciferase expression. In addition, the concentration of PMA used was 5 ng/mL.

5 C. RESULTS

The results of the above assays for a representative compound of this invention, ethyl 2-[N-(1'-aminocitraconamido)]-4-pentafluoroethylpyrimidine-5-carboxylate (*see* Example 48), as percent inhibition versus control are presented in Figure 4. This figure also indicates activity of β-actin which was employed in these
10 assays as a control cell line indicating effects on transcription. The lack of β-actin activity evidences selectivity of the test compounds for the transcription factors AP-1 and NFκB.

Expressed as IC₅₀'s, the results of these assays on additional test compounds are summarized in Table 3 below. The IC₅₀ values reported in Table 3 are
15 the average of the measurements obtained from the NFκB and AP-1 assays described above.

Based on the above results, representative compounds of this invention were found to be effective at inhibiting the activation of transcription factors (*i.e.*, NFκB and AP-1) involved in gene transcription, and therefore have utility as, for example, immunosuppressive agents.

Example 147

ACTIVITY OF REPRESENTATIVE COMPOUND

IN GRAFT VS. HOST AND CONTACT SENSITIVITY MODELS

The murine popliteal lymph node (PLN) assay is a graft vs. host model that predicts activity of compounds in blocking human transplant rejection. The delayed-type hypersensitivity response to oxazolone is a standard contact sensitivity model. Both of these models are used routinely to evaluate compounds that are used clinically. For example, cyclosporin and cyclophosphamide are active in these models and are used clinically (Morris et al., *Transplantation Proceedings* **22**(Suppl. 1):110-112, 1990).

A. POPLITEAL LYMPH NODE MODEL

Spleens are removed from donor BALB/c mice and splenocytes are isolated then irradiated (3,000 rads) to prevent donor cell proliferation. After washing and adjusting cell density, 2.5×10^6 cells are injected subcutaneously into the left hind footpad of C3H mice. On day 4, the mice are sacrificed and left popliteal lymph nodes (PLNs) weighed.

A representative compound of this invention is administered once daily by intraperitoneal injection beginning one day before footpad injection (day 0) through day 4. The compound is suspended, immediately prior to use, at a concentration of 5

mg/mL in 0.25% methyl cellulose (Sigma) using a glass-Teflon homogenizer. For doses of 10, 20 and 30 mg/kg, appropriate dilutions of the stock solution are made so that 0.1 mL/10 g body weight is administered by intraperitoneal injection.

B. DELAYED TYPE HYPERSENSITIVITY STUDY

5 On day 0, oxazolone (100 mL of a 3% solution) is applied to the shaved abdomen of mice. On day 7, a challenge application of oxazolone is applied (10 mL) around the right ear. A representative compound of this invention is administered from days -2 to 7 by intraperitoneal injection. The injectable solution is prepared immediately prior to use by suspending the compound in 0.25% methyl cellulose
10 (Sigma) using a glass-Teflon homogenizer. For each dose, 0.1 mL/10 g body weight of the suspension is administered. The compound is prepared at the highest concentration for this study and appropriate dilutions of the stock solution are made so that 0.1 mL/10 g body weight is administered. Twenty four hours later, the difference in right vs. left ear thickness is measured.

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:
Remark: Although claim(s) 22-29
is(are) directed to a method of treatment of the human/animal
body, the search has been carried out and based on the alleged
effects of the compound/composition.
2. ☐ Claims Nos.:
because they relate to parts of the International Application that do not comply with the prescribed requirements to such
an extent that no meaningful International Search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all
searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment
of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report
covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is
restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☐ No protest accompanied the payment of additional search fees.
